Especially advantageous mixtures are obtained when a component of formula I is used together with any one of the following components II: propiconazol, cyproconazol, epoxyconazol, tebuconazol or tetraconazol.

The compound mixtures I+II according to the invention have very advantageous properties for the protection of plants against attack by diseases.

The compound mixtures of the invention can be used to inhibit or to destroy the microorganisms occurring on plants or on parts of plants (the fruit, blossom, leaves, stems, tubers or roots) of various crops of useful plants, while at the same time parts of plants that grow later are also protected against such microorganisms. They can also be used as dressings in the treatment of plant propagation material, especially seed (fruit, tubers, grains) and plant cuttings (for example rice), to provide protection against fungal infections and against phytopathogenic fungi occurring in the soil. The compound mixtures according to the invention are distinguished by the fact that they are especially well tolerated by plants and are environmentally friendly.

The compound mixtures are effective against phytopathogenic fungi belonging to the following classes: Ascomycetes (e.g. Venturia, Podosphaera, Erysiphe, Monilinia, Mycosphaerella, Uncinula); Basidiomycetes (e.g. the genera Hemileia, Rhizoctonia, Puccinia);

Fungi imperfecti (e.g. Botrytis, Helminthosporium, Rhynchosporium, Fusarium, Septoria, Cercospora, Alternaria, Pyricularia and especially Pseudocercospora herpotrichoides); and Oomycetes (e.g. Phytophthora, Peronospora, Bremia, Pythium and Plasmopara).

Target crops to be protected within the scope of the present invention comprise, for example, the following species of plants: cereals: (wheat, barley, rye, oats, rice, sorghum and related species); beets: (sugar beet and fodder beet); pomes, stone fruit and soft fruit: (apples, pears, plums, peaches, almonds, cherries, strawberries, raspberries and blackberries); leguminous plants: (beans, lentils, peas and soybeans); oil plants: (rape, mustard, poppy, olives, sunflowers, coconut, castor oil plants, cocoa beans and groundnuts); cucumber plants: (marrows, cucumber and melons); fibre plants: (cotton, flax, hemp and jute); citrus fruit: (oranges, lemons, grapefruit and mandarins); vegetables: (spinach, lettuce, asparagus, cabbages, carrots, onions, tomatoes, potatoes and paprika); lauraceae: (avocados, cinnamon and camphor); or plants such as maize, tobacco, nuts, coffee, sugar cane, tea, vines, hops, bananas and natural rubber plants, as well as ornamentals (flowers, shrubs, broad-leaved trees and evergreens, such as conifers). That list does not represent any limitation.

The compound mixtures according to the invention are especially advantageous for applications in cereals, especially in wheat and barley; also in vines, rice, bananas, fruit and vegetables.

The mixtures of compounds of formulae I and II are generally used in the form of compositions. The compounds of formulae I and II can be applied to the area or plant to be treated, either simultaneously or in succession on the same day, together with, where appropriate, further carriers, surfactants or other application-promoting adjuvants customarily employed in formulation technology.

Suitable carriers and adjuvants may be solid or liquid and are substances ordinarily employed in formulation technology, for example natural or regenerated mineral substances, solvents, dispersants, wetting agents, tackifiers, thickeners, binders or fertilisers.

A preferred method of applying a compound mixture comprising at least one of each of compounds I and II is application to the parts of the plants that are above the soil, especially to the leaves (foliar application). The frequency and rate of application depend

on the biological and climatic living conditions of the pathogens. The compounds can, however, also penetrate the plants through the roots *via* the soil or water (systemic action) if the locus of the plant is impregnated with a liquid formulation (for example in rice culture), or if the compounds are introduced in solid form into the soil, e.g. in the form of granules (soil application). In order to treat the seed, the compounds of formulae I and II may also be applied to the seeds (coating) either by impregnating the tubers or grains with a liquid formulation of each of the compounds in succession or by coating them with an already combined wet or dry formulation. In addition, in special cases, other methods of application to plants are possible, e.g. treatment directed at the buds or the fruit.

The compounds of the combination are used in unmodified form or preferably together with the adjuvants conventionally employed in formulation technology, and are therefore formulated in known manner, e.g. into emulsifiable concentrates, coatable pastes, directly sprayable or dilutable solutions, dilute emulsions, wettable powders, soluble powders, dusts or granules, or by encapsulation in e.g. polymer substances. As with the nature of the compositions, the methods of application, such as spraying, atomising, dusting, scattering, coating or pouring, are chosen in accordance with the intended objectives and the prevailing circumstances. Advantageous rates of application of the compound mixture are generally from 50 g to 2 kg a.i./ha, preferably from 100 g to 1000 g a.i./ha, especially from 150 g to 700 g a.i./ha. In the case of the treatment of seed, the rates of application are from 0.5 g to 1000 g, preferably from 5 g to 100 g, a.i. per 100 kg of seed.

The formulations are prepared in known manner, e.g. by homogeneously mixing and/or grinding the active ingredients with extenders, e.g. solvents, solid carriers and, where appropriate, surface-active compounds (surfactants).

Suitable solvents are: aromatic hydrocarbons, preferably the fractions containing 8 to 12 carbon atoms, such as xylene mixtures or substituted naphthalenes, phthalates, such as dibutyl or dioctyl phthalate, aliphatic hydrocarbons, such as cyclohexane or paraffins, alcohols and glycols and their ethers and esters, such as ethanol, ethylene glycol, ethylene glycol monomethyl or monoethyl ether, ketones, such as cyclohexanone, strongly polar solvents, such as N-methyl-2-pyrrolidone, dimethyl sulfoxide or dimethylformamide, and vegetable oils or epoxidised vegetable oils, such as epoxidised coconut oil or soybean oil; and water.

The solid carriers used, e.g. for dusts and dispersible powders, are normally natural

- 10 -

mineral fillers, such as calcite, talcum, kaolin, montmorillonite or attapulgite. In order to improve the physical properties it is also possible to add highly dispersed silicic acid or highly dispersed absorbent polymers. Suitable granulated adsorptive carriers are porous types, for example pumice, broken brick, sepiolite or bentonite; and suitable nonsorbent carriers are e.g. calcite or sand. In addition, a great number of pregranulated materials of inorganic or organic nature can be used, such as especially dolomite or pulverised plant residues.

Depending on the nature of the compounds of formulae I and II to be formulated, suitable surface-active compounds are non-ionic, cationic and/or anionic surfactants having good emulsifying, dispersing and wetting properties. The term "surfactants" will also be understood as comprising mixtures of surfactants.

Especially advantageous application-promoting adjuvants are also natural or synthetic phospholipids from the series of cephalins and lecithins, such as phosphatidylethanolamine, phosphatidylserine, phosphatidylglycerol and lysolecithin.

The agrochemical compositions generally comprise 0.1 to 99 %, preferably 0.1 to 95 %, of compounds of formulae I and II, 99.9 to 1 %, preferably 99.9 to 5 %, of a solid or liquid adjuvant and 0 to 25 %, preferably 0.1 to 25 %, of a surfactant.

Whereas commercial products will preferably be formulated as concentrates, the end user will normally employ dilute formulations.

Such formulations form part of the present invention.

The Examples that follow serve to illustrate the invention, "active ingredient" denoting a mixture of compound I and compound II in a specific mixing ratio.

Biological Examples

A synergistic effect exists whenever the action of the active ingredient combination is greater than the sum of the actions of the individual components.

The action E to be expected for a given active ingredient combination obeys the COLBY formula and can be calculated as follows (COLBY, S.R. "Calculating synergistic and antagonistic responses of herbicide combination". Weeds, Vol. 15, pages 20-22; 1967):

ppm = milligram of active ingredient (=ai) per litre of spray mixture

X = % action by active ingredient I using p ppm of active ingredient

Y = % action by active ingredient II using q ppm of active ingredient and

E = the expected action of active ingredients I+II using p+q ppm of active ingredient (additive action):

according to Colby:
$$E = X + Y - \frac{X \cdot Y}{100}$$

If the action (O) actually observed is greater than the expected action (E), then the action of the combination is superadditive, i.e. there is a synergistic effect.

O/E = synergy factor (SF).
